

Danger Level 2 - Moderate

Wet and gliding snow represent the main danger.

From the early morning as a consequence of warming during the day and solar radiation there will be a gradual increase in the danger of moist avalanches. As the day progresses individual small and, in isolated cases, medium-sized wet and gliding avalanches are possible. This applies on extremely steep slopes at intermediate and high altitudes, as well as in all aspects. Moist avalanches can be released by people or triggered naturally.

Snowpack

The conditions remain spring-like. Outgoing longwave radiation during the night was severely restricted over a wide area. The surface of the snowpack cooled hardly at all during the overcast night and will already soften in the late morning.

Shady slopes and above approximately 2200 m: The snowpack is largely stable and its surface has a melt-freeze crust that is strong in many cases. Sunny slopes: The snowpack will become wet all the way through as the day progresses.

Tendency

Gradual increase in avalanche danger as a consequence of the precipitation.
