

Danger Level 1 - Low

Tendency: Increasing avalanche danger 

on Wednesday 24 01 2024

Wet snow

Snowpack stability: **poor**

Frequency: **few**

Avalanche size: **small**

Wind slab

Snowpack stability: **poor**

Frequency: **few**

Avalanche size: **small**

2200m

Moist snow slides as the day progresses.

From the early morning as a consequence of warming during the day and solar radiation there will be a gradual increase in the danger of moist snow slides. Individual gliding avalanches can also occur. The avalanches are rather small. The avalanche prone locations are to be found on very steep grassy slopes and in steep rocky terrain.

Southern border of Aran: Some fresh snow and the small wind slabs can be released by a single winter sport participant in isolated cases on very steep shady slopes above approximately 2200 m. The avalanche prone locations are to be found in particular adjacent to ridgelines and in gullies and bowls.

Snowpack

The rain gave rise during the course of the night to slight softening of the snowpack.

Shady slopes: The snowpack is well consolidated and its surface consists of loosely bonded snow lying on a melt-freeze crust that is strong in many cases.

Above approximately 2000 m there are 50 to 60 cm of snow. At low altitude from a snow sport perspective, in most cases insufficient snow is lying.

Tendency

Wednesday: Slight increase in danger of wet and gliding avalanches as a consequence of warming during the day.
