

Danger Level 2 - Moderate

Tendency: Constant avalanche danger →
on Monday 29 December 2025

Wind slab

Snowpack stability: **poor**

Frequency: **some**

Avalanche size: **medium**

Wet snow

Persistent
weak layer

Snowpack stability: **poor**

Frequency: **some**

Avalanche size: **medium**

Wind slabs and weakly bonded old snow are to be assessed with care and prudence. Gliding avalanches and moist snow slides during the day require caution.

The fresh snow and all the wind slabs must be evaluated with care and prudence in particular on very steep shady slopes. This snow is lying on top of a weakly bonded old snowpack in particular on rather lightly snow-covered shady slopes. Fresh and somewhat older wind slabs are sometimes deep and prone to triggering. They are covered with new snow in some cases and therefore difficult to recognise. As a consequence of new snow and a moderate to strong southeasterly wind, further wind slabs will form by Sunday in particular on north and west facing slopes. Sometimes dry avalanches are medium-sized.

As a consequence of warming during the day and solar radiation more gliding avalanches and moist snow slides are possible as the day progresses, but they will be mostly small.

In particular in the southeastern half of Aran the avalanche prone locations are more prevalent and the danger is greater. Ski touring and other off-piste activities, including snowshoe hiking, call for experience and restraint.

Snowpack

30 to 40 cm of snow, and even more in some localities, fell in the last few days above approximately 1500 m. Steep sunny slopes: As a consequence of mild temperatures and solar radiation the snowpack settled. Shady slopes intermediate and high altitudes: The new snow and wind slabs are poorly bonded with the old snowpack. Released avalanches and field observations confirm this situation.

Sunday: Some snow will fall in the next few hours in particular at the southern and eastern borders of

Aran. In particular adjacent to ridgelines and in pass areas high altitudes: The southeasterly wind will transport the new snow.

At intermediate altitudes there are 50 to 100 cm of snow, and even more in some localities. At elevated altitudes snow depths vary greatly, depending on the influence of the wind.

Tendency

Monday: The danger of dry avalanches will decrease gradually. The danger of moist avalanches will increase a little during the day.
