

## Danger Level 2 - Moderate

**Tendency: Increasing avalanche danger**  
on Wednesday 29 January 2025

Wind slab

Snowpack stability: **poor**

Frequency: **some**

Avalanche size: **small**

### Wind slabs at high altitude.

As a consequence of new snow and southwesterly wind, mostly small wind slabs formed at intermediate and high altitudes. These can in some cases be released by a single winter sport participant. The avalanche prone locations are to be found adjacent to ridgelines and in pass areas above approximately 2400 m.

At low and intermediate altitudes the avalanche situation is generally favourable.

### Snowpack

Up to high altitudes rain fell during the day in particular at the southern border of Aran. 5 cm of snow, but less in some localities, will fall in the next few hours above approximately 1500 m. The southwesterly wind will transport the new snow. As a consequence of falling temperatures the snowpack will consolidate during the course of the night.

In particular adjacent to ridgelines: Even in moderately steep terrain there is a danger of falling on the icy crust.

Above the tree line snow depths vary greatly, depending on the influence of the wind. In all regions less snow than usual is lying.

### Tendency

Slight increase in danger of dry avalanches as a consequence of new snow and wind.
