

Danger Level 2 - Moderate

Tendency: Increasing avalanche danger
on Wednesday 3 December 2025

Persistent
weak layer

Snowpack stability: **poor**

Frequency: **few**

Avalanche size: **medium**

Weak layers in the old snowpack are difficult to recognise.

Weak layers in the lower part of the snowpack can still be released in some places in particular on very steep shady slopes. They are barely recognisable. Stability tests and field observations indicate the existence of a weak snowpack on very steep shady slopes. In isolated cases the avalanches in these locations are medium-sized.

Also extremely steep shady slopes: As a consequence of the new snow dry snow slides are possible.

Snowpack

Up to 5 cm of snow, and even more in some localities, fell on Sunday above approximately 1500 m. The fresh snow of recent weeks and the sometimes deep wind slabs are poorly bonded with the old snowpack in some places in particular on shady slopes above approximately 2100 m. Faceted weak layers exist in the bottom section of the snowpack.

In particular at elevated altitudes snow depths vary greatly, depending on the influence of the wind.

Tendency

10 cm of snow, and even more in some localities, will fall until Wednesday. Significant increase in danger of dry avalanches as a consequence of the snowfall. Gradual decrease in danger of moist avalanches as the temperature drops.
